Abstract: The Three Phase Voltage Source Inverter supplies invariably required variable voltage and frequency of the adjustable speed drive system. A number of pulse width modulation (PWM) schemes are used to obtain variable voltage and frequency supply from an inverter. The most widely used PWM scheme for a Three Phase Voltage Source Inverter is carrier based sinusoidal PWM and Space Vector Pulse Width Modulation (SVPWM). There is an increasing trend of using SVPWM, because of their easier digital realization and better DC bus utilization. The study of SVPWM technique reveals that this technique utilizes DC bus voltage more efficiently and generates less harmonic distortion when compared with sinusoidal PWM techniques. The SVPWM technique has become one of the important PWM technique for Three Phase Voltage Source Inverter for the control of AC induction motor, Brushless DC motor, Switched Reluctance motor and Permanent Magnet Synchronous motor. In this paper having collection of different schemes in SVPWM. Specifically various schemes are carrier waveform based modulated reference waveform generation and comparison in SVPWM, Center aligned two level SVPWM, Edge align based sampled reference frame generation in SVPWM, Level shifted multi-carrier concepts based SVPWM and Third order harmonic injection based modulated reference waveform generation and comparison in SVPWM. This paper having simulation results of all the five schemes of SVPWM by using MATLAB/SIMULINK software. The performance of Three Phase Voltage Source Inverter based on various SVPWM schemes are analyzed by various reference parameters like DC bus utilization, Total harmonic distortion (THD), switching stress and efficiency. As a result of these analysis this paper recommends which scheme is more suitable for variable voltage and various frequency drives. The simulation results are provided to validate the proposed model approaches.

Keywords: Three Phase Voltage Source Inverter, Space vector Pulse width Modulation (SVPWM), Modulated reference waveform, Center aligned, Edge aligned, Total Harmonic Distortion (THD), Switching Stress.

1. INTRODUCTION

Three phase voltage source inverters are widely used in variable speed AC motor drive applications since they provide variable voltage and variable frequency output through pulse width modulation control [1] [2]. The most widely used PWM method is the carrier-based sine-triangle PWM method due to simple implementation in both analog and digital realization [2] [3]. However in this method the DC bus utilization is low (0.5Vdc). This has led to the investigation into other techniques with an objective of improving in the DC bus utilization [1] [3]. The PWM technique termed as Space Vector PWM based on space vector theory was proposed by de Broeck et. Al (1988) and Ogasawara et.al (1989) which offers superior performance compared to the carrier –based sine-triangle PWM technique I terms of higher DC bus utilization and better harmonics performance [3]. Further, this technique offers easier digital realization. The research in PWM schemes has intensified in the last few decades. The main aim of any modulation technique is to obtain a variable output with a maximum fundamental component and minimum harmonics [3] [4].

The problem of underutilization of the DC bus voltage led to the development of the Third harmonic-injection PWM (THIPWM) and Space Vector PWM (SVPWM) [5] [6]. In 1975, Buja developed this improved sinusoidal PWM technique which added a third –order harmonic content in the sinusoidal reference signal leading to a 15.5% increase in the utilization rate of the DC bus voltage. In 1988, Van Der Broeck developed the SVPWM technique which has also increased the utilization of DC bus voltage by 15.5% [7] [8].
In the last three decades there are different SVPWM schemes are developed by various authors. But this paper is mainly focus on important five schemes in SVPWM. The various schemes in SVPWM are a) Carrier waveform based modulated reference waveform generation and comparison in SVPWM, b) Center aligned two level SVPWM, c) Edge align based sampled reference frame generation in SVPWM, d) Level shifted multi-carrier concepts based SVPWM and e) Third order harmonic injection based modulated reference waveform generation and comparison in SVPWM. Here these five techniques have similar results, but their methods of implementation are completely different. With the development of microprocessors SVPWM has become one of the most important PWM methods for three phase inverter. The maximum peak fundamental magnitude of the SVPWM technique is about 90.6% increase in the maximum voltage compared with conventional sinusoidal modulation [12]-[16].

This paper having some collective information regarding various schemes as mentioned above presents in the two level SVPWM based Three Phase Voltage Source Inverter. This paper covers entire concepts presents in all the five schemes and also this paper gives a comparative statement regarding all those five schemes. The comparative statement is developed by the following valuable parameters. The parameters are THD, DC bus utilization, switching stress and efficiency. As a result of this comparative statement the reader can identify which scheme is more suitable for particular drive operation. The simulation results are provided to validate the proposed approaches. The paper organized in ten sections. Section II gives some basic introduction regarding SVPWM techniques. Section III introduces the detailed discussion regarding Third order harmonic injection based modulated reference waveform generation and comparison in SVPWM. Section IV introduces the detailed discussion regarding Edge align based sampled reference frame generation in SVPWM. Section V introduces the detailed discussion regarding Carrier waveform based modulated reference waveform generation and comparison in SVPWM. Section VI introduces the detailed discussion regarding Center aligned two level SVPWM. Section VII introduces the detailed discussion regarding Level shifted multi-carrier concepts based SVPWM. Section VIII gives the detailed comparison between the above mentioned schemes. Section IX shows the extension of the proposed scheme to the Z- source and T- source inverters. Section X concludes the paper.

2. SVPWM Principle’s

Space Vector Modulation (SVM) was originally developed as a vector approach to pulse width modulation (PWM) for three phase inverter. It is a more sophisticated technique for generating sine wave that provides a higher voltage to the motor with lower harmonic distortion [13]. The main aim of any modulation technique is to obtain variable output having a maximum fundamental component with minimum harmonics. SVPWM method is an advance: computation intensive PWM method and possibly the best techniques for variable frequency drive applications.

The principle of pulse width modulation is explained by using the figure-1 [22]. The figure-1 (a) shows a circuit model of a single phase inverter with a center-tapped grounded DC bus. The figure-1 (b) illustrates principles of pulse width modulation.

Figure-1 (a) circuit model of a single phase inverter, Figure-1 (b) pulse width modulation

From the figure-1 (b), the inverter output voltage is determined by the following ways.

1. When \( V_{\text{control}} > V_{\text{triangle}} \) means \( V_{AO} = V_{DC}/2 \)
2. When \( V_{\text{control}} < V_{\text{triangle}} \) means \( V_{AO} = -V_{DC}/2 \)
A Comparative Study of Different Approaches Presents in Two Level Space Vector Pulse Width Modulated Three Phase Voltage Source Inverter

Also the inverter output voltage has the following features.

1. PWM frequency as same as the $V_{\text{triangle}}$ frequency.
2. Amplitude is controlled by the peak value of $V_{\text{triangle}}$.
3. The fundamental frequency is controlled by the frequency of $V_{\text{control}}$.
4. Modulation index (M) is defined as

$$M = \frac{V_{\text{control}}}{V_{\text{triangle}}}; \quad 0 \leq M \leq 1$$

The circuit model of a typical three phase voltage source inverter is shown in figure-2. $S_1$ to $S_6$ are the sin's power switches that shape the output, which are controlled by the switching variables $a$, $a'$, $b$, $b'$, $c$, and $c'$. When an upper switch ($a$, $b$, $c$) are switched ON (ie) $a$, $b$ and $c = 1$, the corresponding lower switches ($a'$, $b'$, $c'$) switched OFF (myself) $a'$, $b'$ and $c' = 0$. The upper switches and lower switches are complimentary to each other. Therefore the ON and OFF states of the upper and lower switches determines the output voltages [22]. The SVPWM is a different approach from PWM modulation based on space vector representation of the voltage in the $\alpha$-$\beta$ plane.

![Figure-2](image-url)

**Figure-2.** Three phase voltage source inverter with a load and neutral point, Figure-3 the relationship between abc reference frame to the stationary dq reference frame

The space vector concept, which is derived from the rotating field of the induction motor, is used to modulate the inverter output voltage. In the modulation technique the three phase quantities can be transformed into their equivalent two-phase quantity either in synchronously rotating frames or stationary frame. From these two-phase components, the reference vector magnitude can be found and used for modulating the inverter output [6] [13] [16] [19]. The process of obtaining the rotating space vector is explained in the following section. Considering the stationary reference frame, let the three phase sinusoidal voltage component be

$$V_a = V_m \sin(wt)$$
$$V_b = V_m \sin(wt - 2\pi/3)$$
$$V_c = V_m \sin(wt - 4\pi/3)$$

[1]

When these three phase voltages are applied to the AC machine it produces a rotating flux in the air gap of the AC machine. This rotating resultant flux can be represented as a single rotating voltage vector. The magnitude and angle of the rotating vector can be found by means of clark’s transformation as shown in figure-3. This gives the relationship between the abc reference frame to the stationary reference frame [22].

$$f_{dqo} = K_s f_{abc}$$

[2]

Where

$$K_s = \frac{2}{3} \begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & -\sqrt{3}/2 & -\sqrt{3}/2 \\ 1/2 & 1/2 & 1/2 \end{bmatrix}$$
\( f_{dqo} = [f_d f_q f_o]^T, \)
\( f_{abc} = [f_a f_b f_c]^T \)

and “f” denotes either a voltage or a current variable.

The relationship between the switching variable vector \([a \ b \ c]^T\) and the line-to-line voltage vector \([V_{ab} \ V_{bc} \ V_{ca}]^T\) is given by

\[
\begin{bmatrix}
V_{ab} \\
V_{bc} \\
V_{ca}
\end{bmatrix} = V_{dc} \begin{bmatrix}
1 & -1 & 0 \\
0 & 1 & -1 \\
-1 & 0 & 1
\end{bmatrix}^T \tag{3}
\]

Also the relationship between the switching variable vector \([a \ b \ c]^T\) and the phase voltage vector \([V_{an} \ V_{bn} \ V_{cn}]^T\) is given by

\[
\begin{bmatrix}
V_{an} \\
V_{bn} \\
V_{cn}
\end{bmatrix} = \frac{V_{dc}}{3} \begin{bmatrix}
2 & -1 & -1 \\
-1 & 2 & -1 \\
-1 & -1 & 2
\end{bmatrix}^T \tag{4}
\]

**Figure-4. The eight inverter voltage vectors (Vo to V7)**

By referring the figure-2 there are eight possible switching combinations of ON and OFF patterns for the three upper power switches. The ON and OFF states of the lower power devices are opposite to the upper one and so are easily determined once the states of the upper power switches are determined. According to equation-3 and 4, the eight switching vectors, output line to neutral voltage (phase voltage), and output line to line voltages in turns of DC link \(V_{dc}\) are given in the table-1. The figure-4 shows the eight inverter voltage vectors (\(V_0\) to \(V_7\)).

For 180° mode of operation, there exist six switching states and additionally two more states, which make all three switches of either upper arms or lower arms ON. To code these eight states
A Comparative Study of Different Approaches Presents in Two Level Space Vector Pulse Width Modulated Three Phase Voltage Source Inverter

in binary (one-zero representation), it is required to have three bits \((2^3 = 8)\). And also, as always upper and lower switches are committed in complementary fashion, it is enough to represent the status of upper or lower arm switches [22]. In the following discussion, status of the upper bridge switches will be represented and the lower switches will be complementary. Let “1” denote the switch is ON and “0” denote the switch is OFF. Table-1 gives the details of different phase and line voltages for the eight states.

As described in Figure-3. This transformation is equivalent to an orthogonal projection of \([a b c]^T\) onto the two-dimensional perpendicular to the vector \([1 1 1]^T\) (the equivalent d-q plane) in a three-dimensional coordinate system. As a result, six non-zero vectors and two zero vectors are possible. Six non-zero vectors \((V_1 \text{ to } V_6)\) sharp the axes of a hexagonal as depicted in Figure-3, and supply power to the load. The angle between any adjacent two non-zero vectors is 60 degrees. Meanwhile, two zero vectors \((V_0 \text{ and } V_7)\) and are at the origin and apply zero voltage to the load. The eight vectors are called the basic space vectors and are denoted by \((V_0, V_1, V_2, V_3, V_4, V_5, V_6, V_7)\).

The same transformation can be applied to the desired output voltage to get the desired reference voltage vector, \(\vec{V}_{ref}\), in the d-q plane. The objective of SVPWM technique is to approximate the reference voltage vector \(\vec{V}_{ref}\) using the eight switching patterns. One simple method of approximation is to generate the average output of the inverter in a small period \(T\) to be the same as that of \(V_{ref}\) in the same period [6] [13].

![Figure-5. Basic switching vectors and sectors, Figure-6. Modulating wave \(V_{ma}\) with Third harmonic injection](image)

### 3. Third Order Harmonic Injection Based Modulated Reference Waveform Generation and Comparison in SVPWM

The inverter fundamental voltage \(V_{AB1}\) can also be increased by adding a third harmonic component to the three-phase sinusoidal modulating wave without causing overmodulation. This modulation technique is known as third order harmonic injection PWM. Figure-6 illustrates the principle of this PWM scheme, where the modulating wave \(V_{ma}\) is composed of a fundamental component \(V_{m1}\) and a third harmonic component \(V_{m3}\), making \(V_{ma}\) somewhat flattened on the top. As a result, the peak fundamental component \(V_{m1}\) can be higher than the peak triangular carrier wave \(V_{cr}\), which boosts the fundamental voltage \(V_{AB1}\). In the meantime the peak modulating wave \(V_{ma}\) can be kept lower than \(V_{cr}\), avoiding the problems caused by overmodulation. The maximum amount of \(V_{AB1}\) that can be increased by this scheme is 15.5% [18]. The injected third harmonic component \(V_{m3}\) will not increase the harmonic distortion for \(V_{AB}\). Although it appears in each of the inverter terminal voltages \(V_{AN}, V_{BN}\) and \(V_{CN}\), the third-order harmonic voltage does not exist in the line-to-line voltage \(V_{AB}\). This is because the line-to-line voltage is given by \(V_{AB} = V_{AN} - V_{BN}\) where the third-order harmonics in \(V_{AN}\) and \(V_{BN}\) cancel out.
and \( V_{BN} \) are of zero sequence with the same magnitude and phase displacement and thus cancel each other [18]. The Matlab/Simulink diagram for this third order harmonic injection SVPWM is shown in figure-7. The main blocks available in the diagram are three phase 50 Hz sinusoidal waveform generator, single phase 150 Hz sinusoidal waveform generator, summer, carrier waveform generator, comparator, the three phase bridge circuit and R-L load. The measurement units are connected to measure the various performance parameters of the three phase voltage source inverter.

**Figure-7. Third order harmonic injection based SVPWM**

The simulation procedure for the above Matlab/Simulink circuit is given below.

a) The first step is to generate three phase 50 Hz sinusoidal waveforms.

b) The second step is to generate single phase 150 Hz sinusoidal waveform.

c) The third step is add these two waveforms, we get the waveforms like modulated sinusoidal reference waveforms.

b) The next step is to compare this modulated reference waveforms with carrier waveform and generate the pulses for that switches presents in the three phase voltage source inverter circuit.

c) The simulated waveforms are available in figure-8 that shows the performance characteristics of three phase voltage source inverter.
A Comparative Study of Different Approaches Presents in Two Level Space Vector Pulse Width Modulated Three Phase Voltage Source Inverters

4. EDGE ALIGN BASED SAMPLED REFERENCE FRAME GENERATION IN SVPWM

A pulse width modulation (PWM) scheme for two level inverters is proposed. The proposed PWM scheme generates the inverter leg switching times, from the sampled reference phase voltage amplitudes and centre the switching times for the middle vectors, in a sampling interval, as in the case of conventional space vector PWM (SVPWM). The SVPWM scheme, presented for multilevel inverters, can also work in the overmodulation range, using only the sampled amplitudes of reference phase voltages. The present PWM technique does not involve any sector identification and considerably reduces the computation time when compared to the conventional space vector PWM technique [14]. The present PWM signal generation scheme can be used for any multilevel inverter configuration. A two-level inverter configuration, using on R-L load is used to verify the SVPWM generation scheme experimentally. The figure-9 represents Matlab/Simulink module of the Edge align based sampled reference frame generation in SVPWM.

![Image of circuit diagram](image)

**Figure-9.** Edge align based sampled reference frame generation in SVPWM

The simulation procedure for the above Matlab/Simulink circuit is given below.

a) The first step is to generate three phase sinusoidal waveforms with magnitude=1V.

b) The second step is to calculate Vmax, Vmin and Vmid.

c) The third step is to calculate the switching time T1, T2, T$_{eff}$, T0 and T$_{off}$.

\[
T_1 = V_{max} - V_{mid} \\
T_2 = V_{mid} - V_{min} \\
T_{eff} = V_{max} - V_{min} \\
T_0 = T_s - T_{eff} \\
T_{off} = \frac{T_0}{2} - T_{min}
\]

[5]

Where

- Vmax – Maximum voltage at the instant of any time in seconds
- Vmin – Minimum voltage at the instant of any time in seconds
- Vmid – Average voltage at the instant of any time in seconds
- T$_1$ – Switch-1 turn ON time period in seconds
The fourth step is to find out the gate signal time period for each phase.

\[ T_{gA} = T_A + T_{off} \]
\[ T_{gB} = T_B + T_{off} \]
\[ T_{gc} = T_c + T_{off} \]  \[6\]

Where

- \( T_A, T_B, T_C \) are switching time for phase sequences a, b and c.
- \( T_{gA}, T_{gB}, T_{gc} \) are switching time for gate signals for phase sequences a, b and c.

e) By using these \( T_{gA}, T_{gB}, T_{gc} \) switching time values we can calculate the line voltages as given below.

\[ V_{ab} = T_{gA} - T_{gB} \]
\[ V_{bc} = T_{gB} - T_{gc} \]
\[ V_{ca} = T_{gc} - T_{gA} \]  \[7\]

f) By using the equations 5, 6 and 7, we can generate the modulated sinusoidal reference waveforms.

g) The next step is to compare this modulated reference waveforms with carrier waveform and generate the pulses for that switches presents in the three phase voltage source inverter circuit.

h) The simulated waveforms are available in figure-10 that shows the performance characteristics of three phase voltage source inverter.
There is an increasing trend of using space vector pulse-width modulation (SVPWM) schemes for driving voltage source inverters because of their easier digital realization and better DC bus utilization.

This paper introduces an carrier waveform based modulated reference waveform generation and comparison in SVPWM technique as shown in figure-11 based on a reduced computation method, which is much simpler and more executable than conventional means without lookup tables or complex logical judgments. The SVPWM scheme is modeled and simulated using MATLAB/SIMULINK and experimentally implemented and verified. The simulation procedure for the above Matlab/Simulink circuit is given below.

a) The first step is to generate three phase sinusoidal waveforms with magnitude = 0.8V.
   \[ V_a = V_m \sin(\omega t) \]
   \[ V_b = V_m \sin(\omega t - \frac{2\pi}{3}) \]
   \[ V_c = V_m \sin(\omega t - \frac{4\pi}{3}) \]

b) The second step is to find out the maximum value and minimum value among these three waveforms by using minmax block in Matlab/Simulink.

c) The third step is to add the maximum and minimum values getting from step-2.

d) The fourth step is, divide the values getting from step-3 by -2. Because the magnitude values of waveform get reduced and the waveforms get opposite polarity.

e) The next step having steps
   a. For phase “a” add \( V_a \) with step-4 waveform
   b. For phase “b” add \( V_b \) with step-4 waveform
   c. For phase “c” add \( V_c \) with step-4 waveform

i) The last step is to compare step-5 waveforms with respect to carrier waveform and generates the pulses for that switch presents in the three phase voltage source inverter circuit.

f) The simulated waveforms are available in figure-12 that shows the performance characteristics of three phase voltage source inverter.
6. CENTER ALIGNED TWO LEVEL SVPWM

By referring the above introductory parts, the SVPWM can be implemented in the following steps. The first step is to generate three phase waveforms Va, Vb, Vc by referring the equation 1.

\[
\begin{align*}
Va &= V_{ms} \sin(wt)
\end{align*}
\]

\[
\begin{align*}
Vb &= V_{ms} \sin(wt - 2\pi/3)
\end{align*}
\]

\[
\begin{align*}
Vc &= V_{ms} \sin(wt - 4\pi/3)
\end{align*}
\]

Where \( w = 2\pi f \) and \( f = 50\text{Hz} \).

The second step is to transforms abc parameters into dq parameters

\[
\begin{align*}
\vec{V}_d &= V_a \cos 0^\circ + V_b \cos 120^\circ + V_c \cos 240^\circ = V_a - \frac{V_b}{2} - \frac{V_c}{2}
\end{align*}
\]

\[
\begin{align*}
\vec{V}_q &= V_a \cos 270^\circ + V_b \cos 30^\circ + V_c \cos 150^\circ = 0 + \frac{\sqrt{3}V_b}{2} - \frac{\sqrt{3}V_c}{2}
\end{align*}
\]

The third step is to calculate Vref magnitude and angle (\( \alpha \)) values from equation 8.

\[
\begin{align*}
\vec{V}_{ref} &= \vec{V}_d + j\vec{V}_q = \sqrt{V_d^2 + V_q^2}
\end{align*}
\]

\[
\begin{align*}
\alpha = \tan^{-1}\left(\frac{V_q}{V_d}\right)
\end{align*}
\]
A Comparative Study of Different Approaches Presents in Two Level Space Vector Pulse Width Modulated Three Phase Voltage Source Inverters

The fourth step is to identify the sector in which the reference voltage space vector is present. It is necessary to know in which sector the reference output lies in order to determine the switching time and sequence. The identification of the sector where the reference vector is located is straightforward. The phase voltage corresponding to eight switching states: six non-zero vectors and two zero vectors at the origin. Depending on the reference voltages, the angle of the reference vector can be determined as per the table-2 [22].

**Table-2. Sector Definition**

<table>
<thead>
<tr>
<th>Sector</th>
<th>Degrees</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$0 &lt; \alpha \leq 60^\circ$</td>
</tr>
<tr>

<td>$240^\circ &lt; \alpha \leq 300^\circ$</td>
</tr>
<tr>
<td>6</td>
<td>$300^\circ &lt; \alpha \leq 360^\circ$</td>
</tr>
</tbody>
</table>

The fifth step is switching time calculation: to determine the time duration of $T_a$, $T_b$ and $T_0$. Consider the reference vector in sector 1 as shown in figure-6.

The volt-second product in sector-1 can be written as

$$ \overline{V_{ref}} \times T_s = \overline{V_1} \times T_1 + \overline{V_2} \times T_2 + \overline{V_0} \times T_0 $$

Where

$$ \overline{V_{ref}} = |V_{ref}| \cos \alpha + j |V_{ref}| \sin \alpha $$

$$ \overline{V_1} = \frac{2}{3} V_{dc} + j(0) $$

$$ \overline{V_0} = 0 $$

$$ \overline{V_2} = \frac{2}{3} V_{dc} \cos \left( \frac{\pi}{3} \right) + j \left( \frac{2}{3} \right) V_{dc} \sin \left( \frac{\pi}{3} \right) $$

The equation-10 can be written as

$$ T_s |V_r| \begin{bmatrix} \cos \alpha \\ \sin \alpha \end{bmatrix} = T_1 \left( \frac{2}{3} V_{dc} \right) \begin{bmatrix} 1 \\ 0 \end{bmatrix} + T_2 \left( \frac{2}{3} V_{dc} \right) \begin{bmatrix} \cos \frac{\pi}{3} \\ \sin \frac{\pi}{3} \end{bmatrix} + 0 \times T_0 $$

From equation 11

$$ T_s |V_r| \sin \alpha = T_2 \left( \frac{2}{3} V_{dc} \right) \sin \frac{\pi}{3} $$

$$ T_2 = \frac{|V_r|}{\frac{2}{3} V_{dc}} \cdot \frac{\sin \alpha}{\sin \frac{\pi}{3}} $$

$$ \therefore T_2 = T_s \cdot \frac{a \cdot \sin \alpha}{\sin \frac{\pi}{3}} $$

where, $a = \frac{|V_r|}{\frac{2}{3} V_{dc}}$
Substitute equation 12 in equation 11 we get a T1

\[ T_1 = T_s \cdot \frac{\sin \left( \frac{\pi}{3} - \alpha \right)}{\sin \left( \frac{\pi}{3} \right)} \]

now, \( T_0 = T_s - (T_a + T_b) \) because, \( T_s = T_a + T_b + T_0 \)

Now generalizing the switching time calculation for entire 6 sectors, therefore

\[ T_a = \frac{\sqrt{3} V_{ref} \cdot T_s \cdot \sin \left( \frac{n\pi}{3} - \alpha \right)}{V_{dc}} \]

\[ T_b = \frac{\sqrt{3} V_{ref} \cdot T_s \cdot \sin \left( \alpha - \frac{(n-1)\pi}{3} \right)}{V_{dc}} \]

\[ T_0 = T_s - T_a - T_b \]

Where \( n = 1, 2, \ldots 6 \) and \( \alpha = 0 \) to \( 60^\circ \). The figure-6 shows the reference vector as a combination of adjacent vectors at sector-1. The following table-3 gives the exact location of \( V_{ref} \) and its Dwell time in each sector [18].

**Table-3. \( V_{ref} \) location and Dwell time**

<table>
<thead>
<tr>
<th>( \vec{V}_{ref} ) Location:</th>
<th>( \theta = 0 )</th>
<th>( 0 &lt; \theta &lt; \frac{\pi}{6} )</th>
<th>( \theta = \frac{\pi}{6} )</th>

<td>( T_b = 0 )</td>
<td>( T_b &gt; 0 )</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

With the space vectors, selected and the switching times or dwell times calculated, the next step is to arrange possible switching sequences. In general the switching sequence design for a given \( \vec{V}_{ref} \) is not unique, but it should satisfy the following two requirements for the minimization of the device switching frequency [18].

a) The transition from one switching state to the next involves only two switches in the same inverter leg, one being switched ON and other being switched OFF.

b) The transition of \( \vec{V}_{ref} \) moving from one sector in the space vector diagram to the next requires no or minimum number of switches.
A Comparative Study of Different Approaches Presents in Two Level Space Vector Pulse Width Modulated Three Phase Voltage Source Inverters

The figure-14 space vector diagram for two-level inverter shown below should satisfy the above two requirements. This space vector diagram is common to all the four possible switching sequences. Only changes in this space vector diagram are the various possibilities of reference vector rotation in each sectors.

The first possible switching sequence in each sector is like, starting with [000] switching sequence and also ends with [000] switching sequence. This will be shown in figure-14.1. The seven segments switching sequence and switching time calculation for each switch for each sector is shown in figure 15.1 to 15.6. Figure 15.1 to 15.6 shows a typical seven segment switching sequence and inverter output waveforms for $\overline{V}_{ref}$ in each sectors. Here $\overline{V}_{ref}$ is synthesized by $\overline{V}_1, \overline{V}_2 \& \overline{V}_0$. The sampling period $T_s$ is divided into seven segments for the selected vectors. The following can be observed. The dwell time for the seven segments adds up to the sampling periods, $T_s = T_a + T_b + T_0$. The design requirement (a) is satisfied. For instance the transition from [000] to [100] is accomplished by turning S1 ON and S4 OFF, which involves only two switches. The redundant switching state utilized to reduce the number of switching’s per sampling period. For T0/4 segment in the center of the sampling period, the switching state [111] is selected, whereas for the T0/4 segments on both sides, the state [000] is used. Each of the switches in the inverter turns ON and OFF once per sampling period. The switching frequency $f_{sw}$ of the devices are thus equal to the sampling frequency $f_{sp}$ ie) $f_{sw} = f_{sp} = 1/T_s$ [18].

The performance parameters of the three phase two level inverters are measured and shown in the figure-16.1 to 16.16.
7. LEVEL SHIFTED MULTI-CARRIER CONCEPTS BASED SVPWM

With reference to the figure 15.1 to 15.6 takes the output from the switches 1 to 6 and compare with carrier signals to produce the pulses for each switches presents in the three phase 2-level SVPWM Inverter power circuit. The performance parameters of the three phase two level inverters are measured and shown in the figure-17.1 to 17.16.

Figure-17.1 to 17.16 Performance of Three phase 2-level SVPWM Inverter

8. COMPARATIVE RESULTS OF ALL FIVE POSSIBLE SWITCHING SCHEMES

The main aim of any modulation technique is to obtain variable output having maximum fundamental component with minimum harmonics. The objective of SVPWM technique is to enhance the fundamental output voltage and the reduction of harmonic content in three phase voltage source inverter. In this paper having different possibilities of switching schemes present in two level SVPWM are compared in terms of THD. The Simulink model has been developed for SVPWM modulated two level three phase voltage source inverter. The simulation work is carried in MATLAB/SIMULINK.

The simulation parameters used are; DC input voltage = 100V, fundamental frequency = 50Hz, ODE solver = ode45 (Dormand-Prince), switching frequency = 12 kHz, modulation index = 0.87, load type = constant Z, load = star connected R-L load, active power = 1kW, inductive reactive power = 1000e-3VAR, filter = second order filters. The performance of two level SVPWM modulated three phase VSI is analyzed by considering parameters. The comparative statements of each parameter are given below.

Table-4. Comparative results statement of all five possible switching schemes

</tbody>
</table>

The above table provides a detailed comparison between all five types of switching schemes presents in the SVPWM techniques. From the details presents in the table we can conclude like the method-I and method-II provides better load voltage and load current compared with other three methods and also the method-II and method-V provides lower values of THD compared with other methods. Each
method had unique features and characteristics that will be varying with respect to types and load parameters.

9. SVPWM Technique for Z-Source and T-Source Inverters

All the above section represents the basic concepts recording SVPWM, the various switching schemes in SVPWM and the performance of 2-level three phase voltage source inverter. The same concepts can be represented in the Z-Source inverter (ZSI) and T-Source inverter (TSI) also. The procedure for switching sequence in ZSI and TSI are same as three phase voltage source inverter except the introduction of a shoot though zero state in ZSI. The following subsequent paper should explain these concepts in details.

10. Conclusion

The SVPWM technique can only be applied to a three-phase inverter and it increases the overall system efficiency. The SVPWM is used for controlling the switching of the machine side converter. Advantages of this method include a higher modulation index, lower switching losses, and less harmonic distortion compared to SPWM. SVPWM research has been widespread in recent years, making it one of the most popular methods for three-phase inverters because it has a higher fundamental voltage output than SPWM for the same DC bus voltage. The SVPWM is significantly better than SPWM by approximately 15.5%. However, the SVPWM technique is complex in implementation, especially in the over-modulation region. SVPWM technique has become the most popular and important PWM technique for three phases VSI for the control of AC induction. This paper has provided a thorough review of the each technique with a special focus on the operation of SVPWM in all the five possible switching schemes. In this paper, Simulink models for all five possible switching schemes has been developed and tested in the MATLAB/SIMULINK environment. This paper discusses the advantages and drawbacks of each switching schemes and their simulation results are compared and analyzed by plotting the output harmonic spectra of various output voltages and computing their total harmonic distortions (THD). As seen from the simulation results the DC bus utilization will be variable for all the five possible switching schemes, but the THD will be varied for every switching sequence. From the simulation results we can come to the conclusion like the methods-II and III switching schemes having less THD when compared to the other two methods of switching schemes. In the future researches there are some possibilities are available for implementing the same switching schemes in three phase ZSI and TSI. Definitely the performance of ZSI and TSI will be varied with respect to its different switching schemes.
